Microsoft Excel

Microsoft Excel is the spreadsheet program that needs no introduction, being one of the most popular application in its category. Included in the Microsoft Office suite, it facilitates data organizing and can run thorough analysis and complex calculations. Excel can organize, manipulate, and present numerical data from anything you can put in it. It supports complex calculations, but also summarizes, consolidates, graphically displays, and makes narrative summaries of the data. The spreadsheet of choice Excel's highlight is the array of formulas it can use to manipulate data. It uses functions to perform simple to complex calculations, from a trivial sum to financial, mathematical and statistical operations, or even engineering and web-related tasks. Designed for complicated data sets and spreadsheet collections as much as it is for simple calculations, it bundles tracing options for precedents and dependents, which work together with other formula auditing tools to help you create a fully-working workbook. Data querying and what-if analysis Data set querying is also possible, and the array of compatible sources is not to be neglected. It includes locally-stored files, some of the most popular database servers, Microsoft Azure, or online sources, Sharepoint, Active Directory, Microsoft Exchange, Facebook, and Salesforce. Moreover, Excel can perform what-if analysis, testing different scenarios and generating forecast worksheets. Visually represent your data to make better decisions Whether you have to perform simple calculations or track your expenses at home, or go bigger and analyze large data sets to determine trends, Excel is a good choice. Aiming to improve your experience, Excel can learn from your activity, auto-completing certain cells and making your job easier. Moreover, it can help you create a summary of your data, which will only guide you towards the best choice when it comes to making a decision. Because the number of lists, tables, and the data they contain is increasing, it is necessary to represent them efficiently. This manual describes how to use Microsoft Excel to analyze and represent data. Briefly, Excel and data analysis include the following basic steps: 1. Identifying the data you need. 2. Storing data. 3. Representing data. 4. Analyzing and drawing conclusions. Lists Lists are a fundamental data structure in Excel because they can be used to form tables. They can be formed using list formulas, as explained later in this manual. Excel assigns a number to each list. A list can be described as an area of the spreadsheet that contains all of the data contained within the list. Lists that are located on the same worksheet are considered to be the same list, even if they have different names. Lists can be classified according to the type of data they contain (such as people, dates, times, cities, and so on). Tables Tables in Excel can be used to display multiple data sets or to display data in a matrix that represents a number. The data sets or data that you include in the table must correspond to the columns and rows of the table. If you need to create a table, you can use a table formula, which is a formula that is contained within a cell that is surrounded by table icons. For more information, see "Creating a Table." Excel also enables you to create multiple tables within a workbook. The main table can contain formulas, but the individual tables can only contain data. These individual tables are referred to as "subtables." Excel automatically includes a table called TableDef in the workbook to contain the setup properties for the main table. You can modify the size of the main table by using the Table.width and Table.height properties. You can also add row numbers to tables using the Table.Header property. You can also add image or clipart files in a table. You can also manage the background color and shading settings. Table cells You can access the data that you have represented in each cell in a table by clicking the cell and, after pressing Ctrl+Shift+Enter, you can access the formula that is contained in each cell in a table. When you edit a cell that contains a table formula, Excel highlights the entire formula as it types. To unhighlight the cell, press Enter
