Is it an iterator-based or a container-based swap? Is it an O(N*log(N)) operation? A: It depends what you mean with "standard library swap". A standard library swap is something that will be called by the std::swap function. It is a standard library function and it has specific requirements. Those are described here. All of those details are implementation-dependent. You don't have to know how the swap() function itself works, you just have to call it. That's why, it's an inline function. That makes the implementation details of the standard library swap some of its own implementation details as well. For vector, it does an in-place swap. That means that swap will modify the contents of the vector, and will not construct a temporary vector. The swap function will use the vector's move-assignment operator to swap the elements. std::vector has a move-constructor that will make a brand new copy of the contents and returns it. So std::vector::swap will do a copy of the vector contents, and will then move the elements of the vector. Since you tagged C++11, the C++11 core language and the C++11 standard library provide generic algorithms for swapping elements of containers. These algorithms use move semantics if available, or copy semantics otherwise. A: There is a swap member function in the vector class which does a move to swap the contents. A: std::vector::swap(T&) (if it exists) 09e8f5149f
